SHA1

The *Secure Hash Algorithm 1* has been standardized by the National Institute of Standards and Technology in 1995 and is besides MD5 the most commonly used hash algorithm in practice. An example for its usage is password-based authentication. In that case, the server does not store the user password in plain text but instead the SHA1 hash value of it. Once the user enters his password and after its received at the server, its hash value is computed and compared to the value stored on the server in order to verify its correctness.

Furthermore, the keyboard of the login terminal shows clear signs of the entered password since after a successful login navigation in the software is only done via arrow keys.

What is the password?

Figure: Fingerprints on the keyboard

Remark: Note the German keyboard layout!
